

FOUNDATIONS OF QUANTUM MECHANICS: ASSIGNMENT 8

Exercise 30: Essay question. (20 points)

Describe the measurement problem of quantum mechanics. (Use formulas where appropriate.)

Exercise 31: Exponential distribution (25 points)

Find the mean and variance of the exponential distribution with parameter λ ; it has density $\rho(t) = 1_{t>0}\lambda e^{-\lambda t}$.

Exercise 32: GRW theory (25 points)

Consider the GRW theory with the constant σ much smaller than the value 10^{-7} m suggested by GRW; say, $\sigma = 10^{-12}$ m. Explain why Heisenberg's uncertainty relation implies that a free electron, after being hit by a GRW collapse, could move very fast. Use the uncertainty relation to compute the order of magnitude of how fast it can be (assuming it was more or less at rest before the collapse); the mass of an electron is about 10^{-30} kg and $\hbar \approx 10^{-34}$ kg m² s⁻¹.

Exercise 33: Poisson process (30 points)

For the Poisson process with rate $\lambda > 0$, determine for any fixed $t_0 > 0$ the distribution of $X_{t_0} = \#\{k \in \mathbb{N} : T_k \leq t_0\}$, the number of events up to time t_0 . Follow two reasonings:

(a) Heuristically, assume that an event occurs in every infinitesimal time interval $[t, t + dt]$ independently of disjoint intervals with probability λdt .

Hint: Divide $[0, t_0]$ in $n \gg 1$ subintervals of length $dt = t_0/n$.

(b) Rigorously, assume that the random variables T_1, T_2, \dots are defined to be $T_k = W_1 + \dots + W_k$ with all waiting times W_k independent and exponentially distributed with parameter λ , i.e., with density $\rho(w) = 1_{w>0}\lambda e^{-\lambda w}$.

Hint:

$$\mathbb{P}(X_{t_0} \geq 2) = \mathbb{P}(W_1 + W_2 < t_0) = \int_0^{t_0} dw_1 \int_0^{t_0-w_1} dw_2 \rho(w_1) \rho(w_2) \quad \text{and}$$

$$\mathbb{P}(X_{t_0} = k) = \mathbb{P}(X_{t_0} \geq k) - \mathbb{P}(X_{t_0} \geq k + 1).$$
